

Gen AI:

My current understanding of GenAI is intermediate; I started using ChatGPT a couple years ago. But shifted away because of ethical reasons, since then I have been using Claude most days. I used it to code, brainstorm, and organize. It helps with many aspects of my professional and scholastic career.

I have recently been using it for coding, trying out the new design feature, and organizing my many deadlines this semester. So as a user I have been getting to know how it works on a daily basis. Installing new skills, connecting my various apps, and using GitHub repositories to help with efficient token usage.

However, on the backend, I'm still very new to it, as I don't totally understand what it's doing, which is one of the shortcomings of a rapidly advancing technology. Using the tools effectively actually takes quite a bit of practice. Yes, they can basically do things on their own now. But the human element takes refining.

Which is something I'm hoping to learn in the class. What makes these more advanced models work, and how can I use them efficiently and effectively in my everyday work? LLMs are huge and extremely complicated. Learning what goes on in the backend will be complementary to what I can create on the front end.

I'd say the piece of GenAI art I enjoy, a brand I follow, made a really interesting video using Seedance 2.5; those models are really impressive. I work in fashion, and being able to create realistic videos with fashion pieces based on an image is really cool.
